

In this paper, double IGUs composed of two glass panels with a cavity gap interposed, restrained via linear top/bottom supports and under a combination of in-plane compressive loads and orthogonal ...

Barometric pressure is a fascinating and often overlooked factor that can significantly affect the performance and durability of insulated glass units. This article aims to provide a ...

Insulating glass units (IGUs) are building components that show a particular structural behavior. Although such structures have many advantages from the point of view of thermal ...

An insulating glass unit is sealed at the particular pressure on the day of manufacture. As the pressure outside the insulating glass unit changes, an imbalance occurs between the internal cavity pressure ...

A simple method was devised for calculating the pressure differences that occur on sealed double glazing units due to the combined effect of changes in temperature and barometric ...

Double glass components have become a cornerstone in modern solar panel design, offering enhanced durability and efficiency. However, their production presents unique challenges that manufacturers ...

This JRC Scientific and Policy Report presents the scientific and technical background of the design of glass components, basing on a complete state-of-the-art overview of the existing national codes or ...

This paper will present analyses of sample rectangular double glazed IGUs with symmetrical and asymmetrical heat-strengthened and tempered glass constructions for positive and negative ...

Various methods have been proposed in standards to evaluate this load sharing, which depends upon the stiffness of the glass panes, the thicknesses of spacer and the size of the DGU.

More specifically, it enables calculation of the increase in gas pressure due to either external loads or climatic actions for IGUs composed of an arbitrary number of glass panes of any ...
